

Okay, let me tackle this query. The user wants a structured medical report for a bone fracture case. The inputs are a model confidence of 0.71 and severity classified as Severe.

First, I need to start with the Severity Assessment. Since the severity is given as Severe, I should explain why it's categorized that way. Maybe mention displacement, location, or involvement of weight-bearing joints. But wait, the user didn't specify the fracture location. Hmm, maybe just go with the given severity and add a note to confirm with clinical findings.

Next, the Urgency Level. Severe fractures usually require immediate attention. So Urgent or Emergency? Probably "Emergency" since severe fractures can lead to complications if not treated quickly.

For Recommendations, the list should include steps like clinical evaluation, imaging confirmation (maybe a CT or MRI if needed), surgical consultation, pain management, and immobilization. Also, advising against movement and following up. Each of these as bullet points.

Treatment Complexity: Severe fractures often need surgery, so High complexity makes sense here.

Wait, the model confidence is 0.71. That's below 1, so maybe mention that while the model is confident, clinical correlation is essential. Should I include that in the Severity Assessment? Or maybe in the Recommendations? Probably in the first section to highlight the confidence isn't 100%, so clinical assessment is crucial.

Also, need to structure everything in markdown with the correct
