

Okay, let's tackle this. The user wants a structured medical report for a bone fracture case. The model confidence is 0.71, and the severity is severe. First, I need to make sure I understand the parameters here. The confidence level is 71%, which is above the typical threshold for a positive detection, but not extremely high. However, the severity is classified as severe, so that's a key point.

Starting with the Severity Assessment. Since the system already classified it as severe, I should explain why that's the case. Severe fractures usually involve things like comminuted fractures, open fractures, or those affecting weight-bearing joints. Maybe mention displacement, involvement of critical structures, or potential complications.

Next, Urgency Level. Severe fractures typically require urgent care, so Urgent or Emergent. But I should check if the confidence affects this. Even with 71% confidence, if the severity is high, the urgency remains urgent. Maybe note that the confidence supports the need for confirmation but doesn't delay treatment.

Recommendations: The user wants a bulleted list. First, immediate imaging review by a specialist. Then, possible surgical consultation. Immobilization like a splint before definitive treatment. Pain management, and monitoring for complications. Also, follow-up imaging to confirm and assess progression.

Treatment Complexity: Severe fractures are usually high complexity. They might need ORIF (open reduction internal fixation), which is a surgical procedure. So Treatment
